ABSTRACT

Background: The purpose of this study was to review the literature to provide a comprehensive description of the Level of Evidence (LOE) available to support the operative technique of distraction ankle arthroplasty for the current generally accepted indications and make a grade of recommendation for each. Methods: A comprehensive review of the literature was performed (November 2010 to January 2011) using the PubMed database. The abstracts from these searches were reviewed to isolate literature that described therapeutic studies investigating the results of distraction ankle arthroplasty. All articles were reviewed and assigned a classification (I-V) of Level of Evidence. An analysis of the literature reviewed was used to assign a Grade of Recommendation for each current generally accepted indication for distraction ankle arthroplasty. Results: There is insufficient evidence based literature (Grade I) to support or refute the procedure for either: post-traumatic ankle arthritis, arthritis associated with ligamentous instability, primary degenerative joint disease, chondrolysis, deformity associated with arthritis, osteochondral defects and congenital ankle abnormalities. Conclusion: Inadequate evidence based literature exists to support or refute all currently accepted indications for distraction ankle arthroplasty and further high quality, scientific studies are needed upgrade to these recommendations.

Level of Evidence: Systematic Review of Level III Studies

Key Words: Ankle Joint; Distraction; Arthroplasty; Systematic Review; Level of Evidence; Grade of Recommendation

INTRODUCTION

There has been growing interest in the operative technique of distraction arthroplasty over the last two decades. It was originally described in a large series by Aldegheri and colleagues in 1994 as an alternative treatment for hip arthritis. Though the exact physiology was not and is not yet fully understood, the procedure appears to have the potential for positive outcomes with less invasive surgery. Since 1994, the procedure has been adapted to the ankle joint with some small to medium scale success.

There has been a significant call for further studies to be produced that examine the efficacy and possible applications for distraction arthroplasty of the ankle. The current generally accepted indications for this procedure include: post-traumatic arthritis, arthritis associated with ligamentous instability, degenerative joint disease, chondrolysis, deformity associated with arthritis, osteochondral defects and congenital ankle abnormalities.

The purpose of this paper was to review the literature to provide a comprehensive description of the Level of Evidence (LOE) available to support the operative technique of distraction ankle arthroplasty for currently generally accepted indications.

MATERIALS AND METHODS

A comprehensive review of the literature was performed between November of 2010 and January of 2011 using the PubMed database and keywords “distraction” and “ankle” and “arthroplasty” revealing 171 articles. The current generally accepted indications for distraction arthroplasty were also separately searched in the PubMed database along with the key words “ankle” and “distraction.” These search terms included: “arthritis,” “chondrolysis,” “deformity,” “trauma,” “osteocondral” and “arthrodiastasis.” The reference list of each pertinent article was reviewed for other relevant papers. Non-English literature without English translation was excluded. The abstracts from these searches were reviewed to isolate literature that described therapeutic studies investigating the results of treatment. A total of thirty such articles were found. The same search criteria were used within the EMBASE health database revealing no other articles.

RESULTS

A summary of the grade of recommendation for or against the current generally accepted indications for distraction ankle arthroplasty is presented in Table 3. Insufficient evidence based literature (Grade I) exists to support recommendation for the use of distraction ankle arthroplasty for any of its generally accepted indications. The largest majority of the papers written on distraction ankle arthroplasty (22/30) were literature reviews and expert opinions. While this Level V evidence showed interest in the topic, it was not valuable in discovering the true efficacy of the technique. Most of these papers came to the conclusion that more high quality studies are needed in this field.

Post-traumatic arthritis

Level of Evidence I-III

In 1999, van Valburg and colleagues presented on 17 patients prospectively followed after being treated with distraction ankle arthroplasty. Thirteen patients had arthritis secondary to a previous fracture while three had arthritis of unknown cause and one had a congenital leg-length discrepancy. Patients were followed for at least 1 year and in some cases 4 to 8 years, with pain questionnaires, range of motion evaluation and radiographic analysis. There was statistically significant improvement \( p < 0.05 \) in pain and physical impairment that lasted to at least two years followup. The study unfortunately enrolled only 17 patients and only presented results found at the 2-year mark.
Marijnissen et al. produced another prospective trial in 2002 along with a small randomized control trial of 17 patients comparing distraction arthroplasty to ankle debridement. In the open prospective study the authors found continued improvement in pain and functional scores between 1 and 3 years followup. This progressive improvement continued throughout the study period. Though this controlled study did not find any statistically significant differences between the two groups in terms of pain and function, members of the distraction group reported better improvement in symptoms. Three members of the control group were eventually treated with distraction arthroplasty as they failed on debridement alone. Again, both studies had small numbers and short lengths of followup, with the average between the two studies being 1 year.

van Roermund and Lefeber completed both a retrospective and a prospective trial examining the results of distraction ankle arthroplasty. They described positive results in terms of physical and functional impairment as well as pain and mobility. No statistical data was presented, recruitment was small and followup was inconsistent.

Two more retrospective studies have been completed by van Valburg (11 patients) and Ploegmakers (27 patients) in 1995 and 2005. They demonstrated 55% and 73% positive outcomes, respectively. Both groups examined the retrospective effects of Ilizarov joint distraction on post-traumatic ankle arthritis.

Grade of recommendation

Based on the small numbers of patients, short length of followup, and under powered statistics of these studies, distraction ankle arthroplasty for the treatment of post-traumatic ankle arthritis has a Grade I recommendation.

Arthritis associated with ligament instability

Though the literature was thoroughly examined, there were no papers that discussed distraction ankle arthroplasty as a treatment for arthritis associated with ligamentous instability. Furthermore, there were no individual cases that discussed this as the primary pathology later treated with distraction arthroplasty. Clinical trials are needed to discover the usefulness of this treatment option.

Primary degenerative joint disease (Osteoarthritis)

There were no therapeutic studies that focused on primary degenerative joint disease as an indication for treatment using
distraction ankle arthroplasty. As mentioned before, the vast majority of the patients described in each series were noted to have post-traumatic arthritis. It is likely that each series contained patients who may have had osteoarthritis without any obvious trauma but these individuals were not separated.

**Grade of recommendation**
Without focused evidence based literature, we are unable to comment on distraction ankle arthroplasty as a treatment modality for primary degenerative joint disease and therefore must assign it a Grade I recommendation.

**Chondrolysis**

There were no Level I, II, III or IV studies which discussed distraction arthroplasty as a treatment method for chondrolysis of the ankle joint. There were two case studies of young patients which described the successful employment of the technique for this condition.

Knabe et al. described a 19-year-old male who developed chondrolysis insidiously and was treated with distraction arthroplasty. After 3 years of followup, she had no symptoms in her ankle with normal range of motion and no pain.

Sabharwal and Schwechter used distraction arthroplasty to treat a 15-year-old male who developed chondrolysis after sustaining an open Gustilo grade II, displaced Salter-Harris III fracture of the distal tibia with a Salter-Harris I fracture of the distal fibula. After 5 years of followup, he was working without restriction and had no complaints in his ankle.

**Grade of recommendation**
Given the paucity of high-quality data on the subject, we must assign a Grade I recommendation for the use of distraction arthroplasty as a treatment for chondrolysis.

**Deformity associated with arthritis**

In Tellisi et al., six of 23 cases underwent a simultaneous supramalleolar osteotomy. These are the only reports of deformity associated with arthritis as an indication for distraction ankle arthroplasty and therefore it must be assigned a Grade I recommendation for its use.

**Congenital abnormality**

No Level I, II, III, or IV studies have been produced that discuss the treatment of congenital ankle abnormality by use of distraction arthroplasty.

Adiela et al. described a single case of a 9-year-old female who had foot and ankle contracture previously treated by traditional bone-setters. She was treated with soft tissue release and slow gradual external fixation and distraction to correct the contracture. After completion of the treatment she was able to weight-bear on a plantigrade foot.

**Grade of recommendation**
We have assigned it a Grade I recommendation.

**Osteochondral defects**

A final indication for the use of distraction arthroplasty in the ankle may be for the treatment of osteochondral defects. Unfortunately, only two papers exist which discuss this option. Belzack and colleagues described a 53-year-old man who presented with ankle pain which proved to be an osteochondral lesion of the talar dome. He was treated with autograft and simultaneous ankle arthrodiasis which led to successful resolution of the lesion.

Rodriguez et al. had the only Level IV evidence with a case series describing the treatment of osteochondral lesions of the talus with cryopreserved talal arlograft and ankle distraction. At the end of 24 months of followup, all six patients reported an improvement in symptoms and none had major complications. The authors felt more investigation was needed to explore this treatment.

**Grade of recommendation**
Due to the nature and volume of the literature available we must assign a Grade I to the level of evidence for distraction arthroplasty as a treatment for osteochondral defects.

**DISCUSSION**

There has been a significant amount of interest in the use of distraction arthroplasty as an alternative to arthrodesis and joint replacement for the treatment of ankle problems. This joint preserving procedure may provide an operative alternative to fusion or replacement and its use may not burn bridges for future interventions. Over the last two decades there has been a significant body of work produced in the Netherlands exploring the possible benefits of the procedure. Unfortunately these have been smaller trials, often retrospective, that have focused mainly on post-traumatic ankle arthritis. To date, no level I randomized, controlled trials have been completed, no published papers have ever utilized a control population against which the results of distraction arthroplasty intervention can actually be compared, and no body of work has shown the benefit of distraction arthroplasty for other pathologies in the ankle. Given the large number of expert reviews which have come out recently, however, there seems to be hope for this as a viable alternative to the more standard arthrodesis and joint replacements. Unfortunately, as of yet there needs to be more investigation to discover the procedures true worth.

There were weaknesses in our paper. Even though a thorough review of the literature was performed there was a significant paucity of scientific papers. The large bulk of the studies available were Level IV and V data and the higher quality research was on a smaller, often under-powered scale. This led directly to our conclusion that more scientific endeavors were needed to assess the efficacy of distraction ankle arthroplasty. A second weakness was our inability to include data that did not have an English translation. Though only a few studies were identified, there does appear...
a body of literature in this category. Finally, we did not discriminate papers based on surgical technique, postoperative management, length of followup, patient satisfaction or clinical results which varied significantly between papers. We included all papers that described using distraction arthroplasty in the treatment of ankle pathology. Further studies will be needed to discern the efficacy of the actual distraction arthroplasty procedure itself once its use has been defined.

CONCLUSION

A comprehensive review of the literature has provided predominantly Level V evidence with far fewer Level II, III, and IV trials for the generally accepted indications for distraction ankle arthroplasty. There was no Level I evidence. The evidence available has created a grade I recommendation for the use of the procedure in all of its generally accepted indications. More high quality, scientific studies are needed to discover the true value of distraction ankle arthroplasty.
